

2. Write a Java program to sort an numeric array. The size of the array will be taken from the user, after he specifies the size all the elements of the array will be taken as input and the array will be sorted.

3. Modify the exercise 2 and Write a Java program to sum values of an array

4. Modify exercise 2 Write a Java program to calculate average value of an array elements

5. Modify exercise 2 Write a Java program to copy an array by iterating the array

6. Modify exercise 2 Write a Java program to find the maximum and minimum value of an array.

7. Modify exercise 2 Write a Java program to reverse an array of integer values

8. Modify exercise 2 Write a Java program to find the duplicate values of an array of integer values

1. create a class called ComplexNumber having 2 data members as number1 and number2. Create a pair of getter and setter for the above. Create a method called computeComplexNumber that will multiply the values of the 2 data members and return it in the form of int. For the above create an array of ComplexNumber having 5 elements and in a loop ask the user to enter number1 and number2 5 times each such that each object of the ComplexNumber hold appropriate values. Finally call the computeComplexNumber on each object of the array to display the result.

9. Modify exercise 2 Write a Java program to find the duplicate values of an array

10. Modify exercise 2 to accept 2 different values in 2 different arrays and find the common elements between two arrays
